Tenki (Android weather app)

What went well?

- Getting the weather data from the API and parsing the response (though it was not simple as I thought)
- Passing the weather data to the user interface of the application

What didn't go well?

- I was going to use a recyclerview for the Forecast activity, but I couldn't figure how to populate the view with the data that I was getting for the API. So rather than populating the view dynamically, I added all the UI components that I need in the view, and then use some layout-constraints to stack them vertically.

What would I do differently next time?

- Refactor my code and remove any redundancy.
- I would hide my API keys by storing them as environment variables rather than hard-coding in the source code.
